Safe Share

Share your screen with clients without sharing what they shouldn't see.

macOS · on-device AI · open source

The problem

Sprint review

Jira open, another client's chat next to it

Debugging with a client

Customer emails, tokens, connection strings

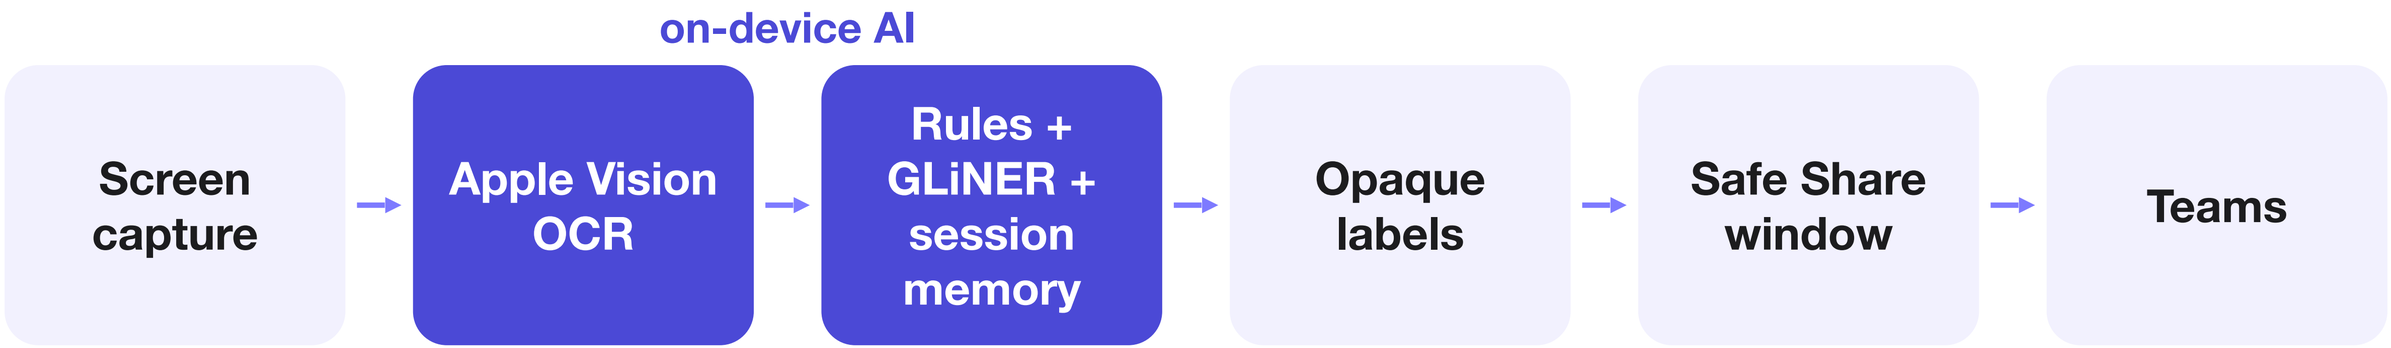

Sales demo

A CRM full of other clients

One frame is an NDA or GDPR problem.

Nobody can watch every pixel while presenting.

How it works

On-device
Screen content never leaves the Mac

Fail-closed
Never a raw frame

Opaque, not blurred
Solid labels over the text

Nothing on disk
No screenshots, no text in logs

In Teams you share one window.

Rules vs. model, measured

Detection	Names masked	Leaks	Harmless lines masked
Rules only	6%	112	2 / 645
+ GLiNER	92%	11	15 / 645
+ GLiNER + session memory	**97%**	**5**	**15 / 645**

Emails and keys have a shape — rules find all of them (emails 18/18, credentials 16/16).

Names don't — a model finds them.

~87 ms

per frame, on the Mac

Synthetic test screens: 8 scenes, 17 screenshots, 118 person names. Also used during development.

Built with AI, built to be reused

How it was built

GPT-6 Astra — idea and first plan

Fable 5.1 — agent workspace, specialized agents, rules

Opus 5 / 5.5 — implementation, with ML, macOS, code review and security agents

Privacy rules written for the agents, checked by review agents

Open source

Apache 2.0

```
uv sync --extra ml
uv run safe-share
```

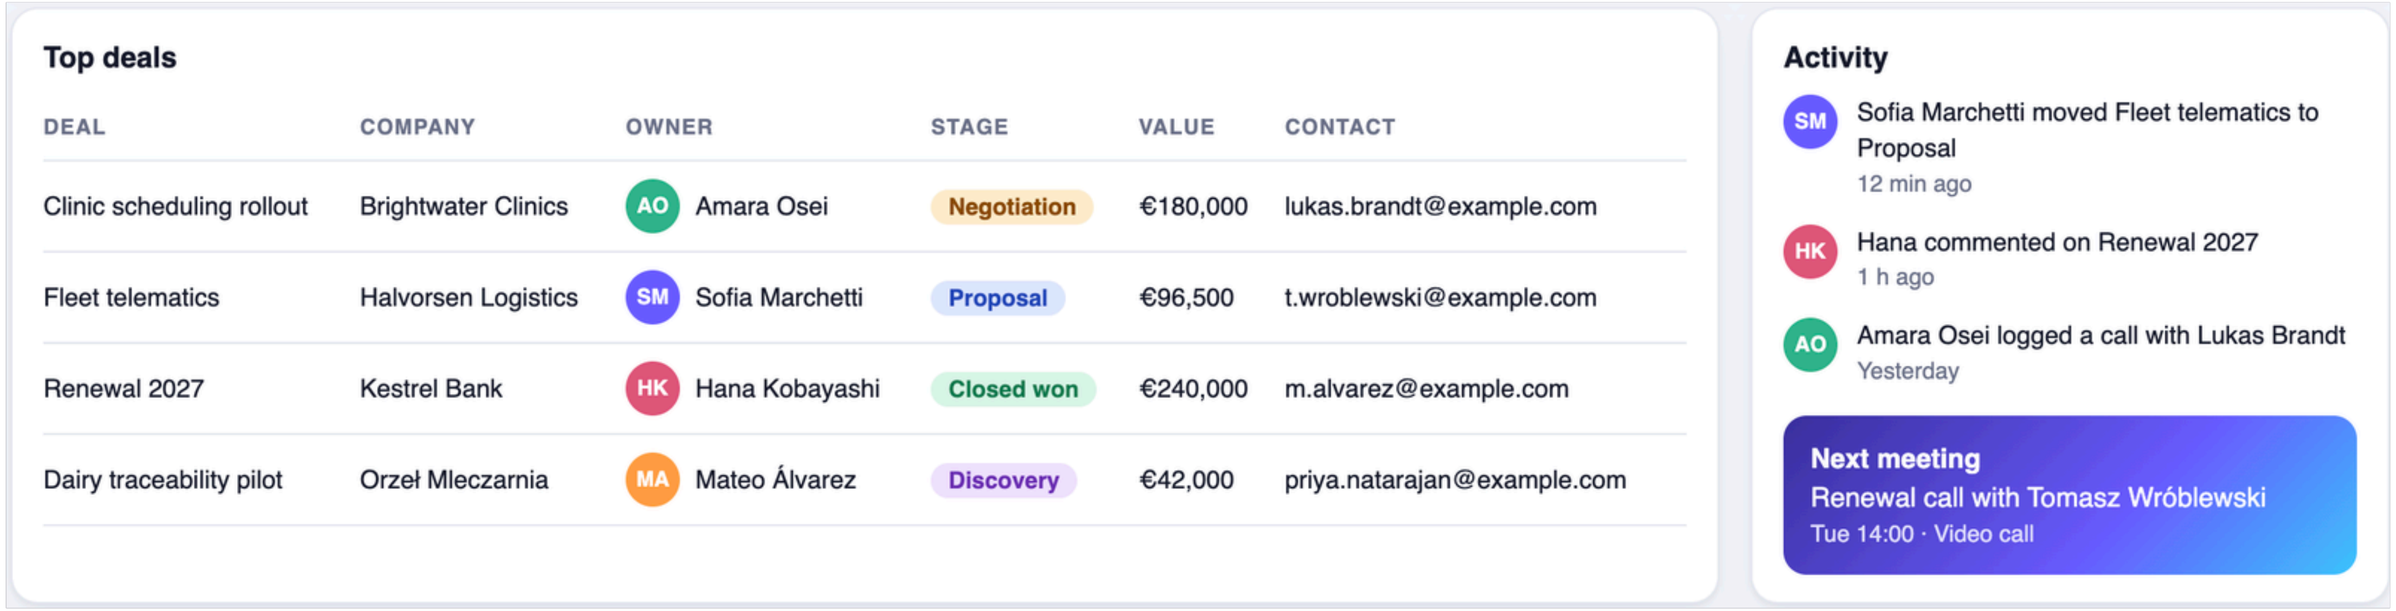

Evaluation runs from the repo

```
detect(texts) -> list[Detection]
```

SECURITY.md · license audit, no copyleft
